Relationship between regions and zones

Region

A region consists of multiple zones. Zones in the same region are interconnected over a low-latency internal network. Zones in each region are completely isolated from zones in other regions.

Zones

The zone in which you want to deploy your resources. Each region has multiple isolated locations known as zones, which have their own independent power supply and network. For example, the China (Qingdao) region has two zones, which are Qingdao Zone B and Qingdao Zone C. Resources that are deployed within the same zone share the same network, and therefore have minimal latency between each other. This means that services deployed within the same zone have faster communication speeds, which translates into more efficient business operations.

The following figure shows the relationships between regions and zones.

- Zones within the same region are interconnected over an internal network. Each zone is independent of each other, providing effective fault isolation. If you distribute your services across multiple zones and one zone fails, services in other zones can continue to serve requests. We recommend that you appropriately distribute your services across multiple zones based on your requirements on disaster recovery and network latency.
- If your application requires high disaster recovery capabilities, we recommend that you deploy instances in different zones within the same region.
- If your application requires low latency, we recommend that you deploy instances within the same zone.

Data Centers Around the World

Regions outside Chinese Mainland

Alibaba Cloud offers an expanding network of CDN nodes and deployment regions, including the first public cloud data center regions in the Middle East (Dubai) and Indonesia, a string of strategic data centers in Asia, and a strong presence in North America, Europe, and Australia.

Regions in Chinese Mainland

Data center regions in China offer BGP backbone network lines providing high-quality coverage country-wide to ensure stable and fast access inside the Mainland. In general, we recommend customers to select the data center closest to their end-users to further speed up online access.

Serving Customers Around the Globe

Alibaba Cloud has 89 zones strategically located across 30 regions in the world, providing reliable computing support for billions of customers.

Network Nodes

Alibaba Cloud Content Delivery Network (Alibaba Cloud CDN) is a distributed network built on top of a carrier network that solves Internet congestion and speeds up access to your web applications. Composed of edge node server clusters in different regions, it replaces the traditional data transmission mode centered on web servers and distributes user requests to the most suitable nodes, allowing the fastest possible retrieval of requested content.

3200+	70+	6
Nodes	Countries	Continents

2300+ nodes in China and 900+ nodes outside the Chinese mainland | 180 Tbps of total bandwidth output capacity
