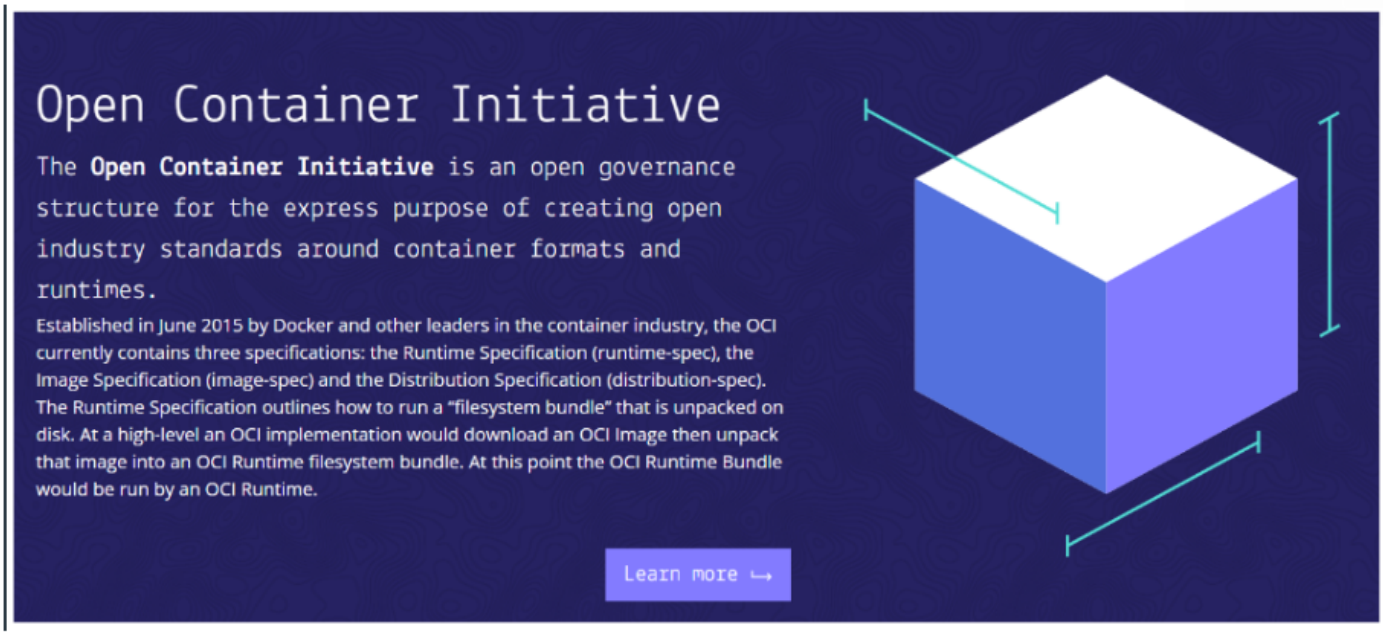
Open Container Standards



[https://opencontainers.org/community/certified/ (https://opencontainers.org/community/certified/)](https://opencontainers.org/community/certified/)

What is Docker?

Docker is an open platform for developing, shipping, and running applications. Let's unpack that statement. By open, Docker means that the software is open source. Anybody can check out the source code and review it for themselves. Docker allows users to build new container images,

push those images to Docker Hub, and also download those images from the Docker Hub. Docker Hub acts as a container image library, and it hosts container images that users build.

What is Podman?

Podman is a daemonless container engine for developing, managing, and running OCI Containers on your Linux System. Similar to Docker, Podman is an open source project. Anybody can check out the source code for the program. Contrary to Docker, Podman does not require a daemon process to launch and manage containers. This is an important difference between the two projects.

Podman seeks to improve on some of Docker's drawbacks. For one, Podman does not require a daemon running as root. In fact, Podman containers run with the same permissions as the user who launched them. This addresses a significant security concern, although you can still run containers with root permissions if you really want to.

Podman seeks to be a drop-in replacement for Docker as far as the CLI is concerned. The developers boast that most users can simply use *alias docker=podman* and continue running the same familiar commands. The container image format is also fully compatible between Docker and Podman, so existing containers built on *Dockerfiles* will work with Podman.

Another key difference is that, unlike Docker, Podman is not able to build container images (the tool Buildah is instead used for this). This shows that Podman is not built to be monolithic.

It handles running containers (among some other things) but not building them. The goal here is to have a set of container standards that any application can be developed to support, rather than relying on a single monolithic application such as Docker to perform all duties.
